ABSTRACT

This paper examines the relationship between patents, appropriability strategies and market for technologies in the English brewing industry before 1850. Previous research has pointed to the apparent oddity that large-scale brewing in this period was characterized both by a self-aware culture of rapid technological innovation, and by a remarkably low propensity to patent. Our study records how brewery innovators pursued a wide variety of highly distinct appropriability strategies, including secrecy, selective revealing, patenting, and open innovation and knowledge-sharing for reputational reasons. All these strategies could co-exist, although some brewery insiders maintained a suspicion of the promoters of patent technologies which faded only in the nineteenth century. Furthermore, we find evidence that sophisticated strategies of selective revealing could support trade in inventions even without the use of the patent system.

In traditional narratives of the Industrial Revolution, the brewing industry occupies a marginal role; and yet large-scale commercial brewing in England underwent rapid technical change across the eighteenth and into the early nineteenth century. To some extent, this marginalization is a simple consequence of the industry’s expansion taking place at a leisurely pace: from 1700 to 1830, the average growth of real output was about 0.5% per year, far lower than in the most celebrated “leading sectors” such as cotton or iron. These figures, however, conceal a remarkable concentration of production which Peter Mathias, whose monumental 1959 volume remains the standard study of the brewing industry in this historical phase, highlights as revolutionary. The technical element of this revolution, Mathias writes, consisted of two broad and interlinked trends: the adoption of mechanized equipment for large-scale production, and process monitoring using quantitative instruments such as the thermometer and saccharometer.

It is remarkable, however, that this vigorous inventive culture was not accompanied by a growth in the use of patents to protect inventions. Indeed, Christine MacLeod, in her authoritative study of the English patent system during the eighteenth century, takes brewing as the archetype of a sector in which inventive activities were carried out outside the coverage of the patent system. Certainly, some patents were taken for brewing-related inventions, yet they were notably infrequent given the profile of the industry. Before the institution of the Patent Office in 1852, securing a patent involved time-consuming bureaucratic procedures and large fees (approximately £100 for England and Wales), and the dangers of litigation were notoriously unpredictable: the effect, some economic historians have suggested, was that patenting activity was skewed towards capital-intensive inventions resulting in large pieces of equipment, for which royalties were easier to collect, cases of infringement were more likely to be detected, and evidence could more easily be presented in court. Since the largest and most highly mechanized breweries displayed not only conscious technological prowess, but a very high degree of capital intensity – being, in fact, among the largest manufacturing concerns of any description – the unpopularity of patents may appear altogether perplexing.

Part of our aim in this paper is to address this apparent anomaly in the light of recent, broader interpretations of the value of patent systems. Some scholars have noted that the establishment of relatively secure, formalized property rights on innovations, such as a patent regime provides, represents a foundational prerequisite for the rise and consolidation of “markets for technologies.” The advantage of a reliably functioning market for technology, the argument runs, is that it enhances the efficient use of technological knowledge throughout the economy: in particular, that it encourages the emergence of a fruitful division of innovative labor in the market between, on the one hand, firms and individual inventors specialized in inventive activities, and, on the other, of firms and entrepreneurs with advanced capabilities in the development and commercialization of innovations.

From this perspective, then, the advantage of the patent system lies not only in the direct incentive to individual inventors to continue to invent, but in the emergence of a general commercial and social context which makes invention and innovation more convenient. These considerations have been stimulated by the findings of Sokoloff and Lamoreaux on the culture of late nineteenth-century

---

US inventors. The American patent system, they suggest, with its comparatively low fees, limited bureaucracy, and efficient administration through the courts, allowed “creative but ambitious inventors to focus on what they did best”, leading to “the most technologically fertile period in American history.” Comparative work by Khan and Sokoloff presents the English system as much less effective in this regard. The earlier investigations of Harold Dutton, however, show that even the pre-1852 regime in England hosted an identifiable class of “quasi-professional inventors”: individuals who specialized in inventive activities broadly considered, taking multiple patents relating to different industries. Dutton’s survey also documents a significant number of cases in which patent rights were traded by means of licenses or assignments. It appears, then, that even the unreformed English system, frustrating as it often was to inventors and investors, functioned well enough to sustain emerging markets in invention. More recent contributions in the economics of innovation literature have pointed out that inventors may be able to exploit their inventions commercially in situations of very weak patents, or even in absence of patent rights.

In what follows, we present a fresh look at the connection between patenting and inventive activities in the English brewing industry, focusing on the extent to which appropriability strategies not based on patents could be effective both for protecting innovations, and for trading them in “markets for technologies”. We begin with a quantitative survey of brewery-related patents in the period in question: this serves to confirm the low incidence that has been noted by prior authors, but it also highlights the complexities of assigning particular inventions to particular industries. We go on to survey the various alternative appropriability strategies used in the brewery, before discussing how early patents were promoted, chiefly by outsiders; and how, ultimately, they began to be accepted in the trade.

**PATENTS IN THE BREWING INDUSTRY, 1634-1850**

Two principal sources, if carefully interpreted, offer a convenient means to identify patents relevant to the brewing industry. The first derives from the Patent Office itself. In 1854, the Superintendent of Specifications, Bennet Woodcroft, oversaw the publication of a Subject-Matter Index which attempted to categorize all identifiable patents according to the trades or industries to which they referred. The category for “Brewing, distilling, rectifying and preparatory processes” is further

---

divided into subcategories including malt preparation, mashing and wort management, clarification of drink, and the more wide-ranging “Brewing and fermenting: malt liquors.”

Woodcroft’s index gives only the titles of patents, but in the 1860s the Patent Office began a long-running project to publish abridgements of specifications, again classified by industry. Class 99 in this series, covering “brewing, wine-making, and distilling alcoholic liquids” in the period 1634-1866, was released by Woodcroft’s successor, Henry Reader Lack, in 1881.

The second major source is the practitioners’ literature on brewing, which by the 1860s was becoming increasingly systematic and technically oriented. The monthly *Brewers’ Journal*, launched 1865, featured a regular “Brewer’s Engineer” column with descriptions and engravings of recent inventions, patented and otherwise; in 1869, the *Journal* serialized a listing of “every patent from 1635 to 1868” under classified headings, a project which was updated regularly in later years. The *Journal* and its rival the *Brewers’ Guardian* were aimed at, and largely written by, self-consciously “progressive” and “scientific” brewers, to whom it was important to affirm a technical history for the trade. This tendency culminated in the work of Henry Stopes (1852-1902), who in the 1880s established himself both as a specialist brewers’ engineer and as an analyst of the malting and brewing trades, contributing historical surveys to the *Journal* and other periodicals. In 1885, alongside an epic bibliography of malting and brewing literature, Stopes published a consolidated “List of patents” since 1634 which he deemed relevant to the industry. Of the 176 patents listed by Stopes in the period up to 1850, 173 also appear in the 1881 Patent Office volume.

Careful analysis of the Woodcroft, Lack and Stopes lists, however, shows that the definition of a “brewing patent” is complicated on several levels. To begin with, a clear distinction between brewing and distilling inventions is frustrated by the fact that several operations are common to both, including the heating of water in bulk, the crushing or grinding of malt, and the ‘mashing’ (infusion in hot water, usually with mechanized stirring) which the malt undergoes to produce fermentable wort. In some such cases, such as the mashing machine patented in 1793 by Edward Biley (himself a brewer), external evidence shows that the patentee was purely or primarily concerned with the beer-brewing market. In other patents, such as that taken out the following year by James Tate, a London ironmonger, for an “invention of applying fire to the coppers [boilers] of brewers and distillers”, the reference to brewing may be entirely speculative.

A further problem arises because there was no consensus on whether inventions in malting should be considered a subset of those in brewing. Though some brewers, at all levels of production, had always made their own malt, the two processes were customarily distinguished both commercially and technically: most malt was prepared by non-brewing maltsters who were either pure specialists or involved in various agricultural enterprises, and who might also supply distillers. It was quite possible, however, for a technological change in malting to have its chief practical effect in the brewery. Highly roasted black malt, which the chemist Daniel Wheeler attempted (ultimately

14 *Brewers’ Journal* 5 (1869), 33-34, and subsequent issues.
17 Peter Mathias, *Brewing Industry*, 94-95.
unsuccessfully) to protect by patent in 1817, was used by the major porter-brewers in a drive for cheaper materials and greater consistency which fundamentally altered the character of the drink; the production of ‘patent malt’ itself, however, settled as a highly restricted niche activity which had no relevance to most maltsters’ practice. Moreover, to the self-consciously “scientific” brewers of the nineteenth century, the single most important goal was a full understanding of the nature of malt and its possible substitution: they therefore championed greater vertical integration, or at least the close involvement of the brewer in technical decisions. Correspondingly, the trade press declared its intended readership to include not only the brewers but the “allied trades”, the Journal adopting the full title of The Brewers’ Journal, and Hop and Malt Trades Review in 1867. Accordingly, when Henry Stopes published his aforementioned patent list in a volume entitled Malt and Malting, devoted mainly to the construction and management of malthouses, he took it for granted that many of his readers would be brewers. Stopes made no attempt to disentangle the two trades in his bibliography, and his patent list, unlike those of the Patent Office, is uncategorized: from his perspective, all the listed patents evidenced the growth of a common technical culture.

It is also important to understand that in assigning patents to industries, the Patent Office clerks worked without deep knowledge of the industries concerned, and erred persistently on the side of inclusion, entering individual patents under as many categories as possible. The 1854 Subject-Matter Index was prepared “from Titles only” (ie, without examination of the full specifications); any mention of malt, brewing, or distillation was sufficient to ensure inclusion. The brief descriptions, furthermore, were worded so as to favor relevance to the category, so that the patentees’ intentions often appear more specialized than was really the case. Andrew Meikle and Robert MacKell’s 1768 patent, for instance, is noted under “Brewing” as describing a “Machine for dressing and cleansing malt”, but under “Agriculture” as a “Machine for dressing wheat, malt and other grain”: examination of the patentees’ backgrounds reveals them as millwrights courting a primarily agricultural audience. Milling and steam-boiler technologies, too, were incorporated on the basis of a passing mention of possible brewery or distillery application. This tendency extends to the abridgement volumes, where the most relevant sections of the specifications were abstracted for the industries in view. Even Stopes, whose professional context made him much more selective about the patents of his own time, was led by outline descriptions to a number of questionable inclusions for the pre-1800 period.

It would not be useful, therefore, to draw conclusions from the listings of Lack and Stopes unmediated. In recording faithfully all patents with any suggestion of a malting or brewing context, however, the two sources provide a useful dataset from which to construct a more careful categorization. Our method has been to appraise each patent based on the full specification, where this is readily available, or, failing this, the Patent Office abridgements or summaries found in periodicals including the Repertory of Arts and Manufactures and Newton’s London Journal of Arts and Sciences (both of which reproduced many specifications in full), the Retrospect of Philosophical, Mechanical, Chemical and Agricultural Discoveries and the Chemist, or in published accounts of litigation. In a number of (mostly pre-1800) cases, specifications were not enrolled or cannot be traced; for these, we have performed as full as possible a cross-comparison of

20 Stopes, Malt, 409.
22 For instance, Stopes includes Walter Taylor’s 1786 patent as describing a “Malt-mill.” Woodcroft excludes the same patent from the brewing category, elsewhere deeming it to refer to “Machines for grinding grain” or “grinding starch for hair-powder.”
any descriptions available. We have also surveyed the principal secondary sources on British brewing and distilling in the period, and have supplemented these with primary research undertaken by one of the authors in preparing a monograph-length study on the development of scientific concepts in the brewery. On the basis of this study, we have been able to assign many of the patents listed in the Stopes and Lack selections to the following categories, chosen to minimize ambiguity.

i. **malting**: innovations in the malt-making process or the construction of malt-houses (not including innovations in the crushing or grinding of malt, which was always carried out by the brewer or distiller).

ii. **brewing**: limited to those innovations which are by nature applicable only in beer-brewing (such as hop extraction or beer cleansing), those specified as intended particularly for beer-brewing, and those known to have been promoted only to beer-brewers.

iii. **distilling**: limited to those innovations applicable only in distilling (such as still-head constructions, condensers, and rectification techniques), those specified as intended particularly for distilling, and those known to have been promoted only to distillers.

iv. **brewing and distilling**: innovations applicable in both industries (such as mashers, boilers and wort refrigerators), and explicitly specified or promoted as relevant to both.

v. **milling, etc**: innovations for the dressing, crushing or grinding of grain, noted as applicable to malt (and thus potentially useful to brewers) but also to products used in other industries.

vi. **boilers, etc**: boilers (including steam-boilers), furnaces, kilns, and heat transmission technologies, specified as relevant to brewing and/or distilling, but also to other industrial processes.

This categorisation excludes a number of patents noted by Stopes or Lack which relate to wine- or cider-making, or which we found to describe general engineering or measurement technologies with no specific drinks-related context.

Since our main concern is with industry attitudes to the decision to patent, our selection criteria privilege the intentions of patentees, where these are known, and exclude the unintended consequences of patenting. The 1780 patent covering the pattern of the Dicas hydrometer, for instance, is assigned to “distilling”, despite evidence that the pattern was later used in the brewery, because the chief aim of the patent was to secure a legislative monopoly which only affected the distillery. Conversely, Matthew Wood’s 1802 patent for a malt-based coloring agent is assigned to “brewing”, despite its reference to refers to “spirits, wines, and other liquors”, since the patent was contrived specifically with an eye to the brewery market.

On this basis, we have constructed Table 1, reporting our assessment of the patents contained in Lack and Stopes lists on the basis of the specifications and the descriptions contained in the contemporary literature; and Table 2, reporting the incidence of relevant patents in different periods, both in absolute numbers and as a proportion of total patenting; and Table 2, reporting our assessment of the patents contained in the Lack list on the basis of specifications and the descriptions contained in the contemporary literature. To the best of our knowledge, ours is the first attempt to reconstruct in detail the volume of brewing related patents in this historical phase.

---

Overall, our results confirm MacLeod’s finding that this industry was characterized by an extremely low propensity to patent throughout the entire period 1634-1850. If we consider as genuine “brewing” patents the patents assigned to the first two rows of Table 1 (i.e., the categories “brewing” and “brewing/distilling”), we find that the share of brewing patents in total patenting is less than 1%.

Table 1 around here

Table 2 around here

We also attempted to extend the analysis to consider the occupations of “brewing” and “brewing/distilling” patentees, drawing this information from the chronological index of English patents constructed by Woodcroft.26 Table 3 reports the percentage shares of different occupations. As noted by MacLeod, the titles ‘gentlemen’ and ‘esquire’ may be regarded as an accurate description of social status only for the seventeenth and early eighteenth centuries: in later years, they were widely adopted as courtesy titles, and may conceal specialist industrial backgrounds.27 The main point of interest emerging from the table, however, is the significant share of patentees who were identifiably “outsiders” to the brewing trade. Even after excluding self-described chemists, engineers, millwrights, and merchants – groups which might have had some direct overlap with the brewery where their inventive activities were concerned – the remaining outsider occupations still account for almost 25% of all patents. This leads us to two conjectures: firstly, that “insider” invention developed principally in a manner invisible to the patent system; and secondly, that the brewing sector held a particular appeal for inventors with backgrounds in other fields, who hoped, by patenting, to benefit from some form of “trade in invention”.

Table 3 around here

With this in mind, in the following sections, we propose a preliminary taxonomy of the appropriability strategies, patent-based and otherwise, adopted by the inventors who targeted the industry. Our survey is based on the secondary sources mentioned above (note 23) and on primary investigations of published literature, brewing records and correspondence held in archives. We distinguish five principal approaches. Firstly, of course, there was the traditional recourse to secrecy. There was also, secondly, a traditional rhetoric of openness, invoked by those who professed to have no commercial interest in their achievements, and by others who claimed that it was impossible, for various technical or economic reasons, to appropriate their work, even given the fullest possible disclosure. Elements of these two approaches were combined in a third, the use of selective revelation as a promotional tool. Fourthly, there was patenting as applied by outsiders, who in practice often struggled to make headway against non-patenting competitors from inside the trade. Finally, however, and only towards the end of the period under discussion, there emerged a category of insiders who saw benefits in patenting themselves. The following sections consider each of these approaches in turn.

**Secrecy**

The most obvious alternative to patenting was silence. Traditionally, the principal techniques of beer-brewing had been considered universal common knowledge, as for baking or other domestic arts. From around 1700, however, commentators began to refer to differences in the methods and products of the large, well-capitalized brewhouses which served the concentrated markets of

---

27 MacLeod, *Inventing*, 117.
London and other major towns. Technical knowledge of processes was typically protected by oral communication, direct demonstration and guild affiliation. Some London apprenticeships around 1740 carried premiums of several hundred pounds: the Brewers’ Company did not control the right to brew, but the fee bought a training and set of connections which were difficult to gain by any other means.

The most notable technical change to emerge within this culture was the rise of the distinctive, well-hopped and dark style of beer known as London porter. Porter production combined efficient use of materials with greatly improved stability in storage, making it uniquely suited to large-scale production; the main points of the innovation were changes to the malt and hop profile and a greatly increased storage time, often by the use of newly developed storage vessels. As the style spread from London to the urban centers of Britain and Ireland across the eighteenth century, porter-brewing gained a tantalizing reputation as a profitable “secret” known to few producers. A popular story emerged which equated the “invention of porter” with a single discrete innovation, supposedly made by an unsung brewer of genius in 1722. This account, in fact telescoped and projected backwards a century of gradual change in a culture which was not necessarily much concerned with the identification or reward of individual inventors. Typical of the transmission mechanism is the case of Nathaniel Chivers, “bred to the porter brewing in London”, who was paid a hundred guineas to bring his knowledge to Glasgow in 1775 under conditions (later breached) of local exclusivity.

Indeed, there are several accounts, by both insiders and outsiders to the brewery, which present secrecy as a defining element of its culture. These usually focus on the extreme lengths to which brewers would go to ensure that production details such as quantities of materials, times and temperatures were protected. Instrument-makers of the nineteenth century routinely supplied brewers with the so-called “blind thermometer”, featuring a traveling index marker and detachable scale. With the scale in place, the brewer could set the marker to a particular value, such as the desired mashing temperature; he would then remove the scale before handing the thermometer to his servant, who would then set the temperature without being able to communicate it. Robert Brakspear, who kept a middle-sized brewery at Henley, Oxfordshire from 1779, made notes using an esoteric system of coded symbols: a square stood for “hours”, a theta for “mild beer”, a diamond for “isinglass.” At the major London firm of Reid’s, written records were “partly faked”, presumably according to an agreed and orally communicated system.

Such colorful strategies are not necessarily representative of the wider culture. The surviving evidence of brewery production logs at all scales of production suggests that most were not intentionally cryptic: all employ some degree of esoteric shorthand, but only so far as is normal in any specialized activity. It is also easy to make too much of the exotic codes and shibboleths of

guild culture, which were of declining relevance: writing in 1760, one time-served member of the London trade claimed that the traditional function of the Brewers’ Company as a regulatory body had broken down entirely around 1730, giving way to an “anarchy” of new entrants looking to get rich quickly. Protecting innovative advantage typically relied on a more mundane strategy of keeping sensitive records and equipment behind closed doors, paying high salaries to skilled staff, and otherwise trusting in the barrier formed by the high degree of tacit knowledge which was needed to turn a profit from most new equipment or methods. If brewers could be secretive, they were often skeptical of “secrets”, in the sense of prescriptions which could be revealed by paper communication. What Nathaniel Chivers’s Glasgow employers contracted to buy from him, for instance, was not a written specification of the London method, but as much on-site practical demonstration as proved necessary.

37 London Chronicle, 22 December, 1760, 603.

40 Best MSS: Jackson to Best, July 21, 1770.

A market for secret specifications did, however, operate to some extent. In 1762, Humphrey Jackson (1717-1801), an apothecary and manufacturing chemist, proposed a course of lectures in which he would explain methods for malting, the analysis of malt, hops and yeast, “the real Causes of Cloudyness in Malt Liquors”, “an easy practicable Method of Brewing Porter in Summer”, and “a most useful new improved Thermometer adapted to the Brewery.” Jackson was probably inspired by his father-in-law, Benjamin Martin, who delivered public lectures to promote sales of the scientific instruments he retailed; yet Jackson’s course was emphatically not public. “As soon as an adequate Sum is subscribed,” he advertised,

the Proposer will execute his Proposals, by way of Lecture, supported with Experiments, at any Time and Place agreed on; after which he will print them at large; and by leaving certain blank Spaces in the Book, to be filled up afterwards in Writing, or by References printed separately, they will be rendered useful to the Subscribers only.38

This was a variation on an old guild device: in the seventeenth century, the Company of Distillers in London had circulated printed lists of process directions to its freemen, with crucial information disguised by symbols which became intelligible once handwritten keys were added. The system had an obvious drawback: the text was later pirated and republished with the keys included (“for the Publike good”).39 Jackson, however, was looking to force the pace of technical change in the brewhouse, and presumably reckoned on being able to keep ahead of any printed disclosures. In the event, it seems the proposed lectures did not take place: Jackson became advisor to the major London porter brewer, Henry Thrale, which put constraints on his communications with other brewers. By 1770, however, he had secured Thrale’s agreement to revive the lecture scheme, provided he advised only “Country Brewers” far from Thrale’s territory.40 The brewers who were instructed under such terms could generally be relied on to stick to confidentiality agreements, as any breach would potentially aid their rivals.

Almost all attempts to gain a premium from secrecy relied on some form of direct attendance, but there were attempts to promote privileged knowledge – or at least the promise of it – by correspondence, via directions in manuscript, or even print. The brewer George Lloyd Worthington, in 1812, sold a book of guidance privately at five guineas (£5.5.0), ten times the price of a more
The intention, of course, was that the extent of the buyer’s investment would itself secure his support in protecting confidentiality. George Adolphus Wigney, brewer and inventor of an unpatented refrigeration system, went much further in 1835, offering a comprehensive treatise privately to major brewers at £100. Supported by testimonials from satisfied customers and employers, he was able to meet his subscription target.

**Openness**

Some innovators, by contrast, professed an attitude of complete openness regarding the content of their innovations, for a variety of reasons. A few claimed – perhaps sincerely – to seek no reward from their discoveries beyond the glory of achievement. A key example is Michael Combrune (d. 1773), the first commercial brewer to publish in detail on trade practices. Combrune’s most crucial achievement was in popularizing the use of thermometers in malting and brewing. Though he had no proprietary interest in any particular device, his system of management itself, based on tabulated relationships between malt colors, mashing heats and the desired keeping qualities of the beer, could have been made the subject of a patent application or promoted privately as a secret. Instead, Combrune first of all offered his system to the London Company of Brewers, to which he belonged, to be held in common for the eyes of Company freemen only; to his surprise, Company officials (perhaps not sharing his opinion of its significance) pronounced him “at full liberty to dispense of it to the public.” This he did in two volumes of 1758 and 1762, which were widely excerpted in the reviewing press. Combrune occasionally acted as a private consultant to other brewers, dispensing information about practical thermometry not found in his books, but made it clear that he did not see this as a principal source of income. His chief aim, in publishing, was to gain acceptance as a chemical theorist.

To others, building a reputation within the trade might have more commercial significance. James Baverstock, a brewer on a middling scale at Alton in Hampshire, discovered (according to his own version of events) the use of the flotation hydrometer to measure wort strength in the 1760s. He initially approached several leading brewers privately with the knowledge; like Humphrey Jackson, he secured the attention of Henry Thrale, who later presented Baverstock with a silver hydrometer in recognition of his achievements. Most brewers were not rivals: only those competing over the same geographical and product markets were in a position to damage each other’s livelihoods, and the greatest brewers could safely exercise a paternalistic attitude towards the rest of the trade. A brewer in Baverstock’s position could, by sharing his innovations, place himself effectively under the patronage of a relative giant such as Thrale: the reward might be an entry into the London market for his product (under terms agreeable to his patron), or the likelihood of employment in the event of the failure of his own business. Like Combrune, Baverstock claimed to be acting in the general interest of the trade; yet unlike Combrune, he did not publish – until John Richardson, the promoter of a proprietary hydrometer, claimed the novelty of the discovery for himself in 1784.
pressing Baverstock to assert his priority. Baverstock also responded by engaging an instrument-maker to develop a hydrometer to his own specification, but from 1786 he was managing partner in an increasingly profitable brewhouse at Windsor, and apparently had neither time nor need to consider marketing innovations as a source of income.47

The dominant porter brewers of London were particularly inclined to strategically open behavior given that, by around 1800, they were heavily insulated from rising competition by the immense capital needed to break into the market at their level of production. They would often flaunt their technical innovations as statements of forward-thinking, economy and reliability, aimed not only at drinkers but at each other. In 1784, Henry Goodwyn, ranked London’s seventh brewer in terms of output, became the first to commission a Boulton and Watt engine; an order from Whitbread, the leading brewer, followed a month later. Boulton and Watt’s design itself was protected, of course, but its installation required various adaptations in the brewhouse must have generated valuable experience; we might expect Goodwyn to have sought patents, or simply to have kept the information to himself. Instead, he went out of his way to offer himself as an advisor to others planning to introduce steam, including his brewery rivals.48 The point was to confirm Goodwyn’s status – notwithstanding that his output was only half of Whitbread’s – within the charmed circle of large-scale brewers. Goodwyn’s magnanimity was intrinsically restricted to that circle: for all their one-upmanship, the greatest brewers made collective agreements on issues such as retail pricing and were in many ways almost a cartel, safe in the knowledge that no competitor could raise the capital to oppose them.49 Unrestricted disclosure, then, was harmless so long as no outsider was in a position to use the information disclosed.

**PARTIAL PUBLICATION WITHOUT PATENTING**

Some innovators sought to combine the advantages of secrecy and openness, publishing accounts of discoveries which were sufficient to demonstrate their expertise, but which could not be applied in practice without private consultancy. The most influential exponent of this approach was John Richardson (1743-1815), mentioned above as the rival of James Baverstock. Richardson had been advertising privately as a consultant for some time when in 1777 he published a short volume, modeled loosely on contemporary chemical treatises, offering “Hints” towards principles which, he said, would direct a more efficient practice.50 In 1784, now established as a successful brewery proprietor in Hull, Richardson engaged a prominent London instrument-maker, John Troughton, to produce a custom-designed hydrometer which he promoted through a second, more detailed treatise.51 Richardson dubbed the new device a “saccharometer,” emphasizing its particular application to the dissolved sugars in brewers’ wort, and claimed to be the pioneer of wort hydrometry. In fact, this approach had been known to some brewers since the 1740s, and Richardson’s priority claim triggered fierce public objections from Baverstock.52 Nonetheless, by carefully presenting himself as a champion of brewers’ interests, Richardson established the saccharometer as an industry standard. To affirm that it was not merely an adapted distillery device,

51 John Richardson, *Statistical Estimates of the Materials for Brewing, or a Treatise on... the Saccharometer* (London, 1784).
52 Richard Clarke, *Notice is Hereby Given, to all Dealers... that the Hydrometer... is now Brought to its Utmost Perfection* (London, [1746]); James Baverstock, *Hydrometrical Observations and Experiments in the Brewery* (London, 1785).
he published a detailed history of the instrument’s calibration, as performed in his own brewhouse using barrels of brewers’ wort.  

There is no evidence that Richardson attempted to patent the saccharometer. From a technical standpoint, he could probably have done so: the design contained novel features such as a sliding “regulator,” designed to correct mechanically for differences in local water, and was at least as distinctive as a hydrometer patented by John Dicas in 1780. Richardson instead prioritized building up his reputation among the brewers. In his publications, Richardson cast himself as a “scientific” (a word which appeared in his titles from 1788) authority, while stressing that he remained a commercial brewer, and would advise primarily on a commercial basis. The physical technology of Richardson’s saccharometer was only one element of an interlinked system which also included the published treatises, direct instruction by personal attendance, and secret manuscripts. The text of one such manuscript found its way into print some years after his death: it does not describe any novel apparatus, but consists largely of operational directions to be carried out using conventional equipment, guided by Richardson’s saccharometer and a thermometer of standard Fahrenheit pattern, along with directions for record-keeping. Richardson’s 1784 treatise retailed at five shillings, and the saccharometer itself at three guineas (£3.3.0); yet the manuscript commanded 150 guineas (£157.10.0) plus a guarantee of twenty years’ secrecy. It is likely, therefore, that Richardson considered he had little to fear from the emulation of his technology by others, provided his authority remained intact. The name “saccharometer” and Richardson’s brewery-specific scaling were, indeed, appropriated by more established hydrometer-makers in his lifetime. Nonetheless, Richardson’s reputation as a key brewing theorist grew and outlived him, as his consultancy, and his own brewery, prospered.

Richardson’s strategy was refined by later consultant brewers such as William Black, who published an extensive treatise in 1835. Black emphasized the importance of chemical theory to effective brewing, paying particular attention to contemporary research suggesting that electrical action could influence the progress of fermentation. Convinced that the unpredictable souring still widely experienced in the most up-to-date breweries was an effect of atmospheric electricity, Black began to promote the comprehensive removal of iron vessels and fittings, and their replacement with electrically insulating materials. The same interpretation was later to form the basis of two patents, including one by Andrew Crosse, an amateur whose electrical research was famous in his day; yet Black, despite setting up several breweries with non-metallic equipment, never patented anything himself.

For a variety of reasons, then, the promoters of brewery innovations – in particular, those who were themselves brewers – often focused on strategies which had no use for the kind of protection afforded by the patent system. Indeed, a consultant such as Black, who expected to live by tutoring and consultancy fees rather than royalties, might positively welcome the early appropriation of his innovations by others.

By the late eighteenth century, large-scale brewers increasingly found themselves dealing with the installation and management of patent technologies aimed at a broad range of industries, such as steam engines and milling machines. There were also a few patents by non-brewers which, though of broad potential scope, were in practice of primarily brewery significance, such as Matthew Wood’s 1802 process for making artificial coloring. Humphrey Jackson, discussed above as a promoter of brewing systems under conditions of secrecy, provides an earlier example: he first came to the attention of the brewing community when he obtained, in 1760, a patent on the production of isinglass. This material, prepared from sturgeon and other fish, was used in a variety of industries, but its chief use was in fining (removing cloudiness from) London porter. By one report, leading brewers combined to gift Jackson “a considerable sum of money” towards the perfection of his process. Jackson was later to invoke his brewery connections in a further scheme involving a chemical process for hardening timber, patented in 1769. Though his chief intended market was always shipbuilding, his circulars to brewing clients pointed out the importance of casks and wooden storage vats to their operations, and the project was largely funded by Jackson’s chief brewery patron, Henry Thrale.

John Long (d. 1807), a few years later, made patenting more central to his approach. Long’s background is obscure: he is described as a “Merchant” of Longville, County Dublin, and was apparently a protégé of John Beresford, First Commissioner of the Revenue in Ireland. He was thus enabled, on traveling to England in 1789, to tour the major breweries and distilleries, making investigations of their operations which informed him in taking out two patents the following year. Long’s specifications are notable as the first to describe an entire system of brewing, including innovations in large parts of the process, as opposed to a method or apparatus for an individual task. Most of Long’s proposals involved the use of submerged pipe coils, similar to distillers’ worms, through which hot or cold water would circulate to achieve temperature control in various brewery vessels. In Long’s case, again, we see that patenting was not always viewed as the optimum strategy. Returning to Dublin in 1792, Long petitioned the Irish Parliament stating that he was in possession of a full systematic knowledge of English production, and was willing to negotiate disclosure based either on the granting of an Irish patent to himself, or on remuneration in exchange for a general public disclosure to the Irish brewers. Parliament favored the latter course, and this probably explains Long’s appointment as “General Examiner and Inspector of Breweries” by 1800.

Another patentee of a system of brewing was Richard Shannon, who styled himself “M.D.” but was apparently active as a chemist, distiller and metalware dealer. Shannon’s system of 1798, like
Long's, focused on temperature control, but relied on steam-jackets and similar enclosures to convey hot water, cold water or air. In 1805, he issued a treatise on brewing, distilling and vinegar-making which was, for its time, the most extensive and expensive work on the subject, running to over 1000 pages of lavishly produced quarto and sold by subscription at £2.12.6. The apparently comprehensive work was, in fact, simply a promotional device on a grand scale: the text was built around Shannon’s patent specifications and other descriptions of his equipment, bulked out with lengthy quotations from Richardson, Baverstock and other authors.

The activities of such outsiders inevitably attracted the suspicions of some within the trade, to whom a reliance on patenting might suggest impracticality or imposture. Humphrey Jackson’s involvement with Henry Thrale ended in disaster: Thrale over-committed himself financially to the timber-hardening scheme, and the brewhouse staff blamed Jackson when, in 1772, one of the wooden storage vessels burst apart and the remainder of the year’s production was found to be sour, leaving the firm on the brink of collapse. Instructors and innovators with a brewery background had an obvious interest in excluding the outsiders: Jackson was also attacked by John Richardson, who produced an anonymous pamphlet assailing his “secret system” as dangerous quackery. John Long, in similar fashion, fell foul of George Blake, a trained ale-brewer who operated as a traveling consultant, initially in private. Long had approached Blake as a potential partner, but Blake derided Long’s patent system as absurdly impractical, and was moved to publish for the first time in order to dissociate himself from it. (The experience apparently converted Blake to the value of print: in later years, he published a volume describing the innovations on which he advised privately, again without patenting). Shannon, it appears, was more convincing: the 700 subscribers to his treatise included most of the trade’s conspicuous leaders in London and provincial centers such as Burton upon Trent.

**Patenting as used by “insiders”**

No patentee of an evidently brewing-related invention gave his occupation as “brewer” until 1784, when Sutton Thomas Wood, of Oxford, took out a patent on an approach which could be applied to wort-boiling and to comparable boiling stages in other manufactures. The boiler was to be covered, and the steam conveyed by pipes to perform various useful tasks, such as working a steam engine or providing heat elsewhere in the process. The specification built on a slightly earlier patent in which Wood described modifications to steam-engine design, and was followed by another extending the approach to various other manufactures. A few years later, Wood obtained a fourth and final patent on a steam-driven weaving engine. Wood’s innovations did not, therefore, focus notably on brewing: he might rather be classed with the numerous engineers concerned with improving the efficiency of steam-heating in this period. A self-described “brewer”, in this period, could be anything from an expert in brewhouse technology to a sleeping partner whose interests lay...
elsewhere, and without firm biographical evidence, it is difficult to assess how far Wood could appeal to brewers as a knowledgeable insider. Nonetheless, when the largest breweries began to install steam engines in the 1780s, Wood was in contention as a potential rival manufacturer to Boulton and Watt. 77

From Wood’s time, as suggested by Table 3, a significant minority of brewery-relevant patents come from identifiable brewers. In 1787, James Walker of Dover took out the first patent covering a mechanized mashing-rake. William Ker (d. 1807), said to have erected “one of the completest breweries and distilleries” in Peebles, patented in 1788 a scheme to capture and condense the steam from hop-boiling, in order to recover the essential oil of hops that would otherwise be lost to the atmosphere. 78 Walker’s patent specified particular technical contrivances for carrying out known tasks; Ker’s, the general principle of a proposed reform that could be carried out by various means. Both innovations inspired a number of later patentees, but it is impossible to gauge how far they were actually worked.

The first London brewer to patent was Richard Hare, whose porter brewery at Limehouse had been in his family since at least the 1730s: in 1790 it was ranked the fifteenth-greatest in London on an annual output of 23 000 barrels, putting it on a par with the largest provincial breweries. 79 Hare’s patent of 1791 describes a closed boiler whose stated purpose, as in Ker’s patent, is to minimize the loss of volatile hop oils, although the design was probably more inspired by Wood’s engine: Hare had consulted Wood in 1758. Hare’s apparatus was certainly installed at his own brewery: selling the business in 1792, he licensed the invention to his successors for an annuity of £100 for the remaining term of the patent. On learning of Wood’s prior activities, however, they suspected that Hare’s patent was not secure, and by ceasing to pay the annuity triggered an action from Hare in 1803. With Wood testifying on their behalf, Hare’s patent was duly voided: while the specified purpose of Hare’s apparatus was unquestionably distinct from Wood’s, its operation was held to fall entirely within the detailed conceptual scheme Wood had submitted. 80 Later surveys noted that “Hare’s apparatus is now universally employed in all extensive breweries: the construction is more complete than Wood’s.”81 The art of patenting, like that of brewing, contained many traps for the inexperienced and the poorly connected.

The two most high-profile brewers to hold patents were Edward Biley and Henry Goodwyn, junior, who both enrolled mashing machines in, respectively, 1793 and 1797. Members of the coterie of major brewers were evidently somewhat amenable to paying each other royalties under the patent system: Whitbread introduced a Biley masher after 1796. 82 Goodwyn, son of the abovementioned steam-engine pioneer, was the sixth- or seventh-greatest producer around the time of his patent. Yet the very greatest and most highly capitalized brewers – Whitbread, Barclay Perkins, Meux Reid – held no patents, despite the fact that their frenetic growth led to numerous innovations. Patenting was one possible revenue stream among many, and an uncertain one at that. Nonetheless, the major brewers’ interest in steam enmeshed them indirectly in some of the most high-profile debates on the nature and scope of patent protection. While most of its competitors dealt with Boulton and Watt,

Meux Reid commissioned one of Hornblower and Maberley’s engines; this was the principal case cited when Boulton and Watt successfully sued their rivals for infringement.\textsuperscript{83}

This case is also significant for the light it sheds on the beginnings of what became the specialist class of “brewer’s engineer.” The engineer appointed to the project, Arthur Woolf, found the Meux Reid site particularly productive for testing new refinements; the brewers, for their part, found various uses for his talents, so that Woolf stayed on as a salaried resident consultant until 1806, cementing the relationship by marrying Mrs Meux’s maid.\textsuperscript{84} Woolf’s projects at Meux’s included an apparatus for heating water by waste steam, erected in 1800.\textsuperscript{85} His first patent, for a tubular boiler in 1803, was based directly on his experience of installing two boilers at Meux’s. These were initially designed to replace open-firing of the brewing coppers, the invention being adapted later to supply steam engines.\textsuperscript{86}

From the early nineteenth century, there began to emerge a number of dedicated “brewers’ engineers” who typically had general mechanical engineering training, and might or might not work exclusively on brewery projects. Unlike Woolf, these practitioners were not retained by an individual firm, but consulted for a wide variety of brewers; they were as likely as other mechanical engineers to take out patents, working them directly with their consultancy clients providing a captive market. One of the most active was William Tizard, who positioned himself, in the 1840s, as an experienced brewer who no longer had vested interests in any one brewery, prepared to consult for anyone who agreed to his terms. Tizard took it for granted that his inventions should be protected under patent. His first specification, of 1841, describes a system of innovations across the whole process from malt-crushing to fermentation, including the whimsically named “hystricon” (a rotary device to agitate the grain whilst sparging), “Caloriphagon” (a lamp enclosed in a cooling water jacket to avoid heating the fermenting room), and “Pneumatic Life-protector”, a signal light to show excess build-up of carbonic acid gas in subterranean vaults.\textsuperscript{87} Tizard described all these innovations in detail in an extensive treatise on brewing, first published in 1843. This was an adaptation of the strategy earlier adopted by Richard Shannon; but, where Shannon had merely bulked out his specifications with hack borrowing, Tizard based his work on an exceptionally comprehensive survey of the literature, carefully updating the text between editions to showcase his mastery of the latest knowledge – and to denigrate the approaches and apparatus offered by rivals.\textsuperscript{88} Tizard never licensed his patents: the actual installation of apparatus, like his more general advisory consultancy, was centrally maintained and fully private.

**CONCLUSIONS**

Recent studies of patenting activities, both contemporary and historical in focus, have pointed to significant intersectoral differences in the effectiveness of patents as a tool for protecting inventions.\textsuperscript{89} Our study, based on the detailed analysis of inventive activities, shows that it is important to acknowledge differences in appropriability strategies even within the same industry. The case of the English brewing industry displays widespread and persistent behavioral

heterogeneity: it might perhaps be regarded as a complex ecological system, in which inventors could develop different strategies fit to ensure survival in specific niches. No one approach, therefore, was “typical” or “characteristic” of the industry at any given time. There is, however, evidence of a widespread insider presumption against patenting, which was often associated with unreliable outsiders, until around the turn of the nineteenth century. To adequately account for the later shift to embrace patent protection would require further study, although it seems reasonable to suppose that the increasing appeal to brewers of technologies developed in more patent-friendly settings – most obviously, the steam engine – played a major role.

Perhaps our most important finding, as demonstrated by the case of John Richardson, is that careful selective revealing, and a sophisticated approach to the communication of inventions, could allow a “trade in inventions” to thrive even without the use of the patent system. Furthermore, even when inventors opted for an appropriability strategy based on patent protection, patents were only one ingredient of the mix: promotion through technical books and pamphlets, drawing on the past strategies of both patenting and non-patenting innovators, remained a key strategic factor. Given the growing interest in markets for technologies, it would be instructive to establish how far this pattern was peculiar to the English brewing industry, and how far it represents a more widespread phenomenon.
